

GIT COMMANDS WITH SIMPLE DESCRIPTION

git status - Shows you which files you changed, what's ready to commit, and what's not tracked yet. Always run this first!

git add . - Adds ALL your current changes (new files, modified files, deleted files) to the "staging area" so Git knows what to save.

git commit -m "message" - Takes everything you added with git add and saves it permanently in Git's history. The message should describe what you did.

git push - Sends your committed changes from your computer to GitHub/GitLab/Bitbucket (the online storage).

git pull - Gets the latest changes from the online storage and adds them to your computer. Use this before starting work!

git clone <url> - Copies an entire project from GitHub to your computer. You only do this once per project.

git init - Turns a regular folder on your computer into a Git repository (makes Git start tracking it).

git log - Shows you a list of all the commits (saves) you and others made, with who made them and when.

git branch - Shows all the different "branches" (versions) of your project. You're probably on "main" or "master".

git checkout <branch-name> - Switches you to work on a different branch. Like changing channels on TV.

git diff - Shows you exactly what lines you added, changed, or deleted in your files.

git restore <filename> - Throws away your changes to a file and brings it back to how it was last saved.
